HYDROLOGIC ATLAS OF THE BLACK HILLS, PENNINGTON COUNTY, SOUTH DAKOTA

Structure Contour Maps

Structure Contour Map: A map showing by means of contour lines of equal elevation the shape of the surface of a selected rock layer (contact) beneath the Earth’s surface.

ROCKERVILLE QUADRANGLE

The sedimentary formations within the Rockerville Quadrangle are affected by a regional tilt (dip) of eight to ten degrees to the east. This dip is interpreted, however, by folds (anticlines and synclines) in which the west limbs dip to the west as much as 30°.

Inyan Kara Group: (see map)

Although portions of the Lakota Formation are exposed along the eastern margin of the Rockerville Quadrangle, the upper surface of the Inyan Kara Group on, which the contours are located, is not. Therefore, construction of a contour map is not possible for this unit here.

Minnelusa Formation: (see map)

The Minnelusa Formation trends northerly through the central portion of the quadrangle. Structure contours reveal that the upper contact of the unit, located along the east side of the recharge area, extends from the surface, at elevations of approximately 4,200 feet, to an elevation as low as 2,800 feet along the eastern margin of the quadrangle, a horizontal distance of about three and one-half miles.

In addition to the overall eastward dip, four folds disrupt the surface. The folds display parallel anticlinal-synclinal axes, which are located along sharp bends in the contour lines. One fold in the northeast corner of the quadrangle crosses from the Rapid City West Quadrangle on the north and ends against a fault near to Spring Creek. The other three fold pairs, e.g., the Rockerville Anticline which lies immediately west of Crystal Cave, plunge generally to the south or southeast. Maximum structural relief across the Rockerville Anticline is 300 feet. Each fold extends beyond the east or south margin of the quadrangle.
Figure. Cross section illustrating the gentle east dip of sedimentary layers within the Rockerville Quadrangle.

**Madison aquifer (Pahasapa Limestone): (see map)**

The Pahasapa Limestone (Madison aquifer) trends northerly through the west-central portion of the quadrangle. Structure contours reveal that the upper contact of the unit, located along the east side of the recharge area, extends from the surface, at elevations of approximately 4,200 feet, to an elevation as low as 2,300 feet along the eastern margin of the quadrangle, across a horizontal distance of about four miles.

In addition to the overall eastward dip, four large folds and two smaller ones affect the surface. The folds display parallel anticlinal-synclinal axes, which are located along sharp bends in the contour lines. The largest anticline bifurcates about two miles south of the north margin of the quadrangle, forming two southeast plunging folds: both extend to the eastern edge of the quadrangle and beyond. Dips in the west limb of the northern segment are as much as 40° to the southwest. Crystal Cave lies along the crestal portion of the anticline where it crosses a small canyon.

The northeastern-most fold plunges south-southeast. Three other fold pairs plunge generally to the southeast. All four folds extend beyond the east or south margins of the quadrangle. Three smaller folds in the southern portion of the quadrangle plunge southeast and two of these extend beyond the boundary of the quadrangle.
